I'm running CentOS 6.4.5 x64 with 4GB of RAM installed. I've noticed that on a reboot the system consumes more and more memory as the service started after reboot. This memory is not released by any restart of the service. I tried searching the web to see if there was any answers but I couldn't find anything. Here is a list of services that I have, although I don't know which started after the system was reboot. All of them are running, although I'm unable to track which one may be causing the problem: But as you can see, service memory is increasing, up to 10 or 20GB. The only packages I installed after reboot are from freenx (freenx.log shows the process has memory leaks but I don't know what I have to do to fix it). So, what's wrong with my system and how can I clean up the memory? A: Those services are instances of daemon-like processes that you start after system boots. They start running as you are logging in and after that they will run on every boot and you don't have to do anything more. They will probably stay, unless you or they stop them. If you think they are memory hogs, don't worry about it. You haven't said what they are for, so you may not even know. You can delete them and it won't break anything, as long as they are not critical for your system. EDIT: To address your comment: if you stop the process, the system will free those memory blocks, as memory manager has a number of "reserve" blocks that are pre-allocated memory and when you use a block it is moved to one of these reserved blocks. Since you don't have any, and the block is used, the manager will free it. However, after each boot, the system will free the blocks in
